

OrderUp CafØ POS - Pitch

Problem

Small cafØs often juggle handwritten tickets, edited orders, split payments, and kitchen updates manually.

Generic POS demos usually look polished but skip the awkward real-life cases that staff actually handle.

Solution

OrderUp is a compact Angular + Spring Boot + MySQL POS for cafØ service.

Cashiers can take and edit orders, kitchen staff can progress ticket status, and bills can be paid or split.

AI Feature

The cart-based add-on recommender checks the live cart against the real menu and suggests a missing category.

It works locally without an API key, and can optionally use OpenAI to polish the wording.

Why It Is Explainable

The backend has simple entities: MenuItem, Order, OrderItem, and Payment.

Business logic lives in one OrderService and one AiRecommendationService.

The Angular frontend is one focused POS screen backed by a small API service.

Demo Flow

Start MySQL with docker compose, run Spring Boot, then run Angular.

Add Latte and Croissant, accept the AI add-on suggestion, send to kitchen, move status, then split payment.
